- (b) Each metallic tank with large unsupported or unstiffened flat surfaces, whose failure or deformation could cause fuel leakage, must be able to withstand the following test, or its equivalent, without leakage or excessive deformation of the tank walls:
- (1) Each complete tank assembly and its supports must be vibration tested while mounted to simulate the actual installation.
- (2) Except as specified in paragraph (b)(4) of this section, the tank assembly must be vibrated for 25 hours at an amplitude of not less than $\frac{1}{32}$ of an inch (unless another amplitude is substantiated) while $\frac{2}{3}$ filled with water or other suitable test fluid.
- (3) The test frequency of vibration must be as follows:
- (i) If no frequency of vibration resulting from any r.p.m. within the normal operating range of engine speeds is critical, the test frequency of vibration must be 2,000 cycles per minute.
- (ii) If only one frequency of vibration resulting from any r.p.m. within the normal operating range of engine speeds is critical, that frequency of vibration must be the test frequency.
- (iii) If more than one frequency of vibration resulting from any r.p.m. within the normal operating range of engine speeds is critical, the most critical of these frequencies must be the test frequency.
- (4) Under paragraphs (b)(3)(ii) and (iii) of this section, the time of test must be adjusted to accomplish the same number of vibration cycles that would be accomplished in 25 hours at the frequency specified in paragraph (b)(3)(i) of this section.
- (5) During the test, the tank assembly must be rocked at the rate of 16 to 20 complete cycles per minute, through an angle of 15° on both sides of the horizontal (30° total), about the most critical axis, for 25 hours. If motion about more than one axis is likely to be critical, the tank must be rocked about each critical axis for 12½ hours.
- (c) Except where satisfactory operating experience with a similar tank in a similar installation is shown, nonmetallic tanks must withstand the test specified in paragraph (b)(5) of this section, with fuel at a temperature of 110° F. During this test, a representative

- specimen of the tank must be installed in a supporting structure simulating the installation in the airplane.
- (d) For pressurized fuel tanks, it must be shown by analysis or tests that the fuel tanks can withstand the maximum pressure likely to occur on the ground or in flight.

[Doc. No. 5066, 29 FR 18291, Dec. 24, 1964, as amended by Amdt. 25–11, 32 FR 6913, May 5, 1967; Amdt. 25–40, 42 FR 15043, Mar. 17, 1977]

§25.967 Fuel tank installations

- (a) Each fuel tank must be supported so that tank loads (resulting from the weight of the fuel in the tanks) are not concentrated on unsupported tank surfaces. In addition—
- There must be pads, if necessary, to prevent chafing between the tank and its supports;
- (2) Padding must be nonabsorbent or treated to prevent the absorption of fluids;
- (3) If a flexible tank liner is used, it must be supported so that it is not required to withstand fluid loads; and
- (4) Each interior surface of the tank compartment must be smooth and free of projections that could cause wear of the liner unless—
- (i) Provisions are made for protection of the liner at these points; or
- (ii) The construction of the liner itself provides that protection.
- (b) Spaces adjacent to tank surfaces must be ventilated to avoid fume accumulation due to minor leakage. If the tank is in a sealed compartment, ventilation may be limited to drain holes large enough to prevent excessive pressure resulting from altitude changes.
- (c) The location of each tank must meet the requirements of §25.1185(a).
- (d) No engine nacelle skin immediately behind a major air outlet from the engine compartment may act as the wall of an integral tank.
- (e) Each fuel tank must be isolated from personnel compartments by a fumeproof and fuelproof enclosure.

§25.969 Fuel tank expansion space.

Each fuel tank must have an expansion space of not less than 2 percent of
